Day 2: Basic Probability | HackerRank

Terms you'll find helpful in completing today's challenge are outlined below.

Event, Sample Space, and Probability

In probability theory, an experiment is any procedure that can be infinitely repeated and has a well-defined set of possible outcomes, known as the *sample space*, S. We define an *event* to be a set of outcomes of an experiment (also known as a subset of S) to which a probability (numerical value) is assigned.

The probability of the occurrence of an event, A, is:

Here are the first two fundamental rules of probability:

1. Any probability, $P(A)$, is a number between 0 and 1 (i.e., $0 \leq P(A) \leq 1$).
2. The probability of the sample space, S, is 1 (i.e., $P(S) = 1$).

So how do we bridge the gap between the value of $P(A)$ and the sample space? Quite simply, since we know that $P(A)$ is the probability that event A will occur, then we define $P(A')$ (also written as $P(A^c)$) to be the probability that event A will *not occur* (the *complement* of $P(A)$). If our sample space is composed of the probabilities of A's occurrence and non-occurrence, we can then say $P(A) + P(A') = 1$, or the sum of all possible outcomes of A in the sample space is equal to 1. This is the third fundamental rule of probability: $P(A^c) = 1 - P(A)$.

Question 1
Find the probability of getting an odd number when rolling a 6-sided fair die.

Given the above question, we can extract the following:

- Experiment: rolling a 6-sided die.
- Sample space (S): $S = \{1, 2, 3, 4, 5, 6\}$.
- Event (A): that the number rolled is *odd* (i.e., $A = \{1, 3, 5\}$).

If we refer back to the basic formula for the probability of the occurrence of an event, we can say:

Compound Events, Mutually Exclusive Events, and Collectively Exhaustive Events

Let's consider 2 events: A and B. A *compound event* is a combination of 2 or more simple events. If A and B are simple events, then $A \cup B$ denotes the occurrence of either A or B. Similarly, $A \cap B$ denotes the occurrence of A and B together.

A and B are said to be *mutually exclusive* or *disjoint* if they have no events in common (i.e., $A \cap B = \varnothing$ and $P(A \cap B) = 0$). The probability of *any* of 2 or more events occurring is the *union* ($\cup$) of events. Because disjoint probabilities have no common events, the probability of the union of disjoint events is the sum of the events' individual probabilities. A and B are said to be *collectively exhaustive* if their union covers all events in the sample space (i.e., $A \cup B = S$ and $P(A \cup B) = 1$). This brings us to our next fundamental rule of probability: if 2 events, A and B, are disjoint, then the probability of either event is the sum of the probabilities of the 2 events (i.e., $P(A \text{ or } B) = P(A) + P(B)$).

If the outcome of the first event (A) has no impact on the second event (B), then they are considered to be *independent* (e.g., tossing a fair coin). This brings us to the next fundamental rule of probability: the multiplication rule. It states that if two events, A and B, are independent, then the probability of both events is the product of the probabilities for each event (i.e., $P(A \text{ and } B) = P(A) \times P(B)$). The chance of *all* events occurring in a sequence of events is called the *intersection* (∩) of those events.

Question 2
Find the probability of getting 1 head and 1 tail when 2 fair coins are tossed.

Given the above question, we can extract the following:

- Experiment: tossing 2 coins.
- Sample space (S): The possible outcomes for the toss of 1 coin are $\{H, T\}$, where $H = heads$ and $T = tails$. As our experiment tosses 2 coins, we have to consider all possible toss outcomes by finding the Cartesian Product of the possible outcomes for each coin: $S = \{\{H, T\} \times \{H, T\} = \{(H, H), (H, T), (T, H), (T, T)\}$.
- Event ($A \cap B$): that the outcome of 1 toss will be H, and the outcome of the other toss will be T (i.e., $A = \{(H, T), (T, H)\}$.

Connecting this information back to our basic formula for $P(A)$, we can say:

Question 3
Let A and B be two events such that $P(A) = \frac{2}{5}$ and $P(B) = \frac{4}{5}$. If the probability of the occurrence of either A or B is $\frac{3}{5}$, find the probability of the occurrence of both A and B together (i.e., $A \cap B$).

We can use our fundamental rules of probability to solve this problem:
$|A \cup B| = |A| + |B| - |A \cap B|$
$\Rightarrow P(A \cup B) = P(A) + P(B) - P(A \cap B)$
$\Rightarrow P(A \cap B) = P(A) + P(B) - P(A \cup B)$
$\Rightarrow P(A \cap B) = \frac{2}{5} + \frac{4}{5} - \frac{3}{5} = \frac{3}{5}$
